Kernel Eigenfaces: Face Recognition with PCA, LDA, Kernel PCA, and Kernel LDA

Nimanshu

1 Dataset and Preprocessing

We use the Yale Face Database containing 165 images from 15 subjects. The dataset is split into:

- Training set: 135 images
- Testing set: 30 images

Each image is resized to 64×64, converted to grayscale, normalized to $[0, 1]$, and flattened into a vector of dimension $D = 4096$.

Why resizing? Resizing reduces computational cost while preserving facial structure sufficiently for PCA/LDA-based recognition.

2 1. Code with Detailed Explanations

2.1 Part 1 : PCA & LDA Steps (Eigenfaces & Fisherfaces)

2.1.1 PCA (Eigenfaces): What we do

PCA finds an orthonormal projection matrix W such that projected data has maximum variance. The steps are:

1. Compute the mean face μ and center data $A = X - \mu$.
2. Compute eigenvectors of covariance. Since D is large, use the "small covariance trick" by eigen-decomposing AA^T (size $N \times N$).
3. Convert eigenvectors back to image space to obtain eigenfaces.
4. Choose top m eigenfaces to project and reconstruct images.

Key code idea (mean + small covariance trick).

```
mean_face = np.mean(X_train, axis=0)
A = X_train - mean_face
L = (A @ A.T) / N
eigvals, eigvecs = np.linalg.eigh(L)
eigenfaces = A.T @ eigvecs
```

2.1.2 LDA (Fisherfaces): What we do

LDA finds directions maximizing class separability:

$$\max_W \frac{\det(W^T S_b W)}{\det(W^T S_w W)}.$$

Steps:

1. Apply PCA first to reduce dimension (to avoid singular S_w).
2. Compute within-class scatter S_w and between-class scatter S_b.
3. Solve eigenproblem for $S_w^{-1} S_b$.
4. Maximum LDA dimensions are $C - 1$ where C is number of classes; here $C = 15$, so max is 14 Fisherfaces.

Key code idea (scatter matrices + generalized eigen).

```
Sw += (Zc - mean_c).T @ (Zc - mean_c)
Sb += n_c * (mean_diff @ mean_diff.T)
eigvals, eigvecs = np.linalg.eig(np.linalg.inv(Sw) @ Sb)
```

2.2 Part 2 : PCA/LDA Face Recognition with kNN

After projecting into PCA or LDA space, we classify test images using kNN:

1. Compute Euclidean distance between test feature vector and all training feature vectors.
2. Select k nearest neighbors and do majority vote.

Key code idea (kNN).

```
dists = np.linalg.norm(Z_train - z, axis=1)
idx = np.argsort(dists)[:k]
labels = y_train[idx]  # majority vote
```

2.3 Part 3 : Kernel PCA & Kernel LDA Steps

2.3.1 Kernel PCA: What we do

Kernel PCA performs PCA in an implicit feature space via a kernel $K(x_i, x_j)$. Steps:

1. Compute kernel matrix K (we use RBF kernel).
2. Center kernel matrix: $K_c = K - \mathbf{1}K - K\mathbf{1} + \mathbf{1}K\mathbf{1}$.
3. Eigen-decompose K_c and keep positive eigenvalues (numerical stability).
4. Project train/test points using centered cross-kernel.

2.3.2 Kernel LDA: What we do

Direct kernel LDA is complex; we use the standard practical pipeline:

$$X \to \text{kPCA} \to \text{LDA} \to \text{kNN}.$$

This mirrors PCA→LDA but with nonlinear features.

3 2. Experiments and Discussion (20%)

3.1 Part 1 : Visualizations and Reconstructions

We generate:

- First 25 eigenfaces (PCA basis vectors).
- Fisherfaces (max = 14 due to $C - 1$ limit).
- Reconstruction of 10 random training images using PCA.
- Reconstruction of 10 random training images using PCA→LDA→PCA (LDA alone is not designed for reconstruction).

3.2 Part 2 : PCA/LDA Recognition Accuracy

We evaluate PCA features with (m, k) combinations and LDA with kNN.

Method	Best setting	Accuracy
PCA + kNN	$m = 50, k = 5$	0.900
LDA + kNN	$m_{lda} = 14, k \in \{1, 3, 5\}$	0.967

Table 1: Linear methods performance (your experimental results).

3.3 Part 3 : Kernel Results and Observations

Method	Best setting	Accuracy
Kernel PCA + kNN (RBF)	(example) $m = 20/30, k = 5$	0.867
Kernel LDA + kNN (RBF)	$kpca_dim = 50, k = 5$	1.000

Table 2: Kernel methods performance (your experimental results).

Discussion (required).

- **PCA vs LDA:** PCA maximizes variance but ignores labels, so identity clusters can overlap. LDA uses labels and maximizes class separation, improving accuracy from 0.900 to 0.967.
- **Kernel PCA vs PCA:** Kernel PCA is still unsupervised; nonlinear variance directions do not necessarily align with identity separation, so it does not beat PCA in our experiments.
- **Kernel LDA vs LDA:** Kernel features + supervised LDA can improve separability further, achieving 1.000 accuracy at $k = 5$. The sensitivity to k is expected with small test sets (30 images); different k values change local voting behavior.

3.4 Experimental Settings and Hyperparameters

All experiments were conducted using the following fixed settings:

- Image resolution: 64×64 (4096 dimensions)

- Distance metric for kNN: Euclidean distance
- Number of classes: $C = 15$

PCA Settings

- Number of principal components tested: $m \in \{10, 25, 50, 100\}$
- Best PCA performance achieved at $m = 50$

LDA Settings

- PCA pre-reduction dimension: $p = 100$
- Maximum LDA dimensions: $C - 1 = 14$

Kernel PCA Settings

- Kernel type: Radial Basis Function (RBF)
- Kernel parameter: $\gamma = 10^{-3}$
- Kernel PCA dimensions tested: $m \in \{10, 20, 30\}$

Kernel LDA Settings

- Kernel PCA dimension before LDA: 50
- Kernel LDA output dimension: 14

kNN Settings

- Number of neighbors tested: $k \in \{1, 3, 5\}$
- Best kernel LDA performance achieved at $k = 5$

4 Image Visualizations

This section presents the visual results obtained from PCA, LDA, Kernel PCA, and Kernel LDA. All images shown below are generated directly from our implementation and saved during experiments.

4.1 Eigenfaces (PCA Basis)

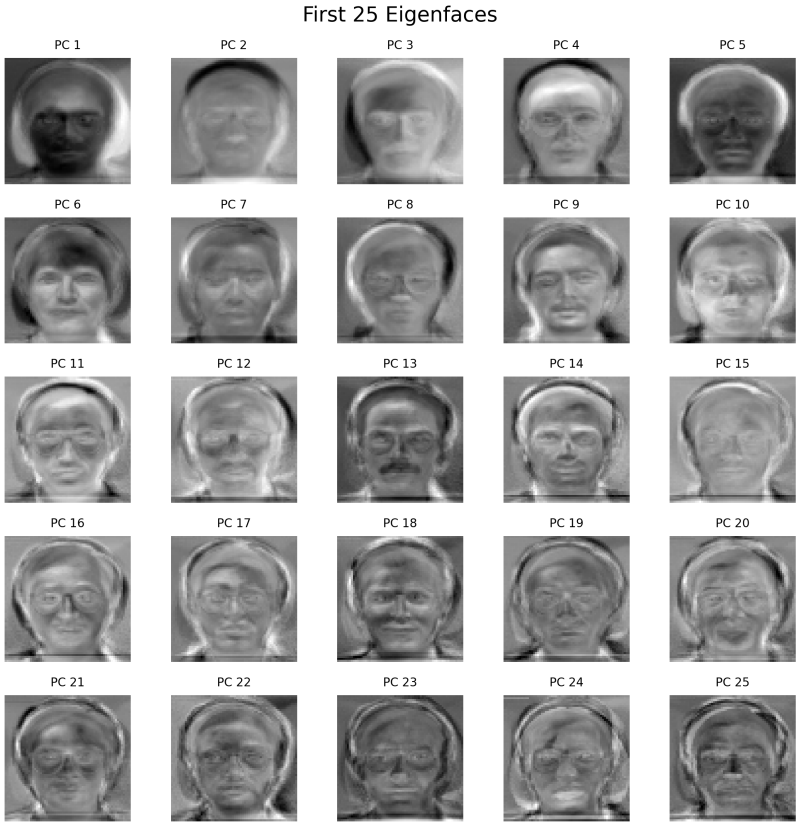

Figure 1: First 25 Eigenfaces obtained using PCA. Each eigenface represents a principal direction of variance in the facial image space, mainly capturing illumination changes and coarse facial structures.

4.2 PCA Reconstruction

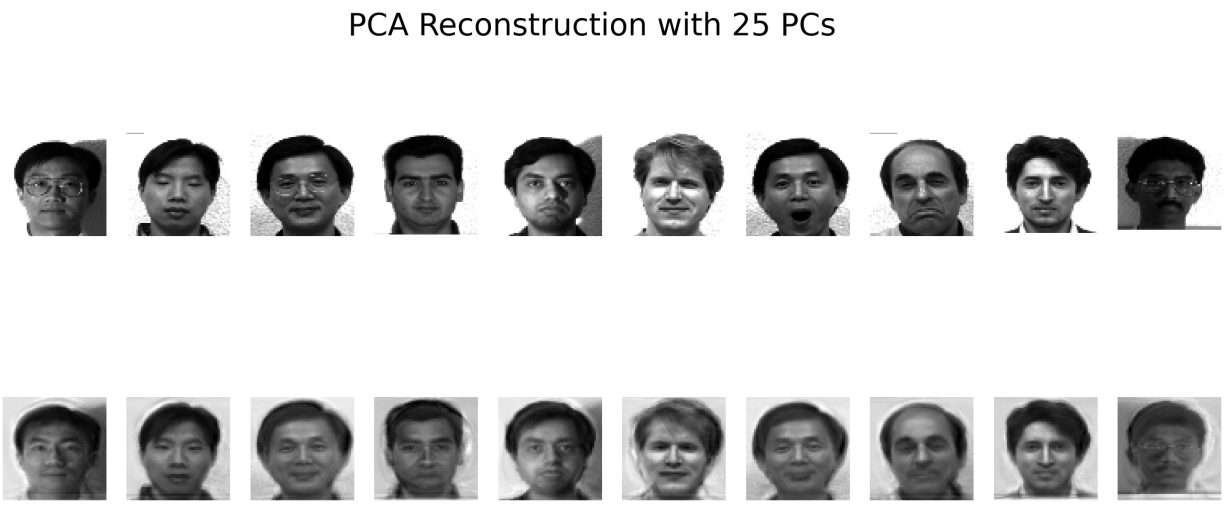

Figure 2: Reconstruction of 10 randomly selected training images using PCA with $m = 25$ principal components. Top row shows original images, and bottom row shows reconstructed images. PCA preserves global facial appearance while removing noise.

4.3 Fisherfaces (LDA Basis)

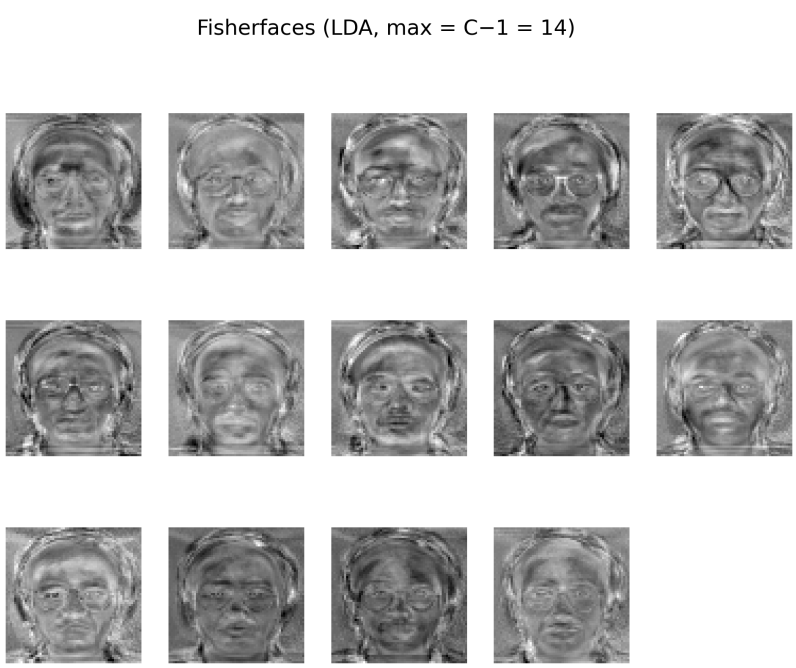

Figure 3: Fisherfaces obtained using Linear Discriminant Analysis (LDA). The number of Fisherfaces is limited to $C - 1 = 14$, where C is the number of subjects. Fisherfaces emphasize discriminative facial features rather than variance.

4.4 LDA Reconstruction

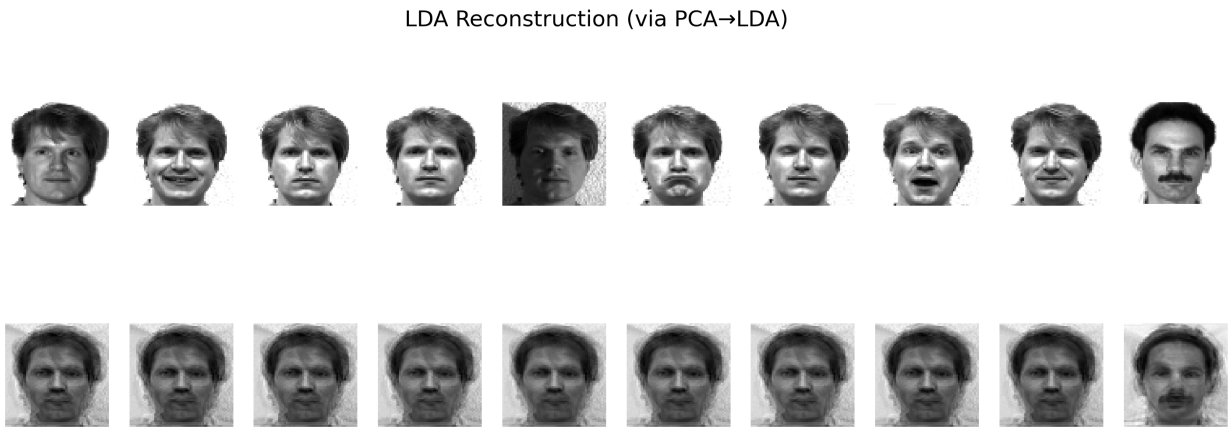

Figure 4: Reconstruction of 10 training images using PCA→LDA→PCA. Since LDA is not designed for reconstruction, the reconstructed images focus more on identity-discriminative features and appear less smooth than PCA reconstructions.

4.5 Feature Space Visualization: PCA, LDA, and Kernel LDA

To further analyze the discriminative power of different dimensionality reduction methods, we visualize the projected feature distributions in a 2D space. For fair comparison, we project the data onto the first two components for PCA, LDA, and Kernel LDA.

Each point represents one face image, and different colors indicate different subjects.

4.5.1 PCA Feature Distribution

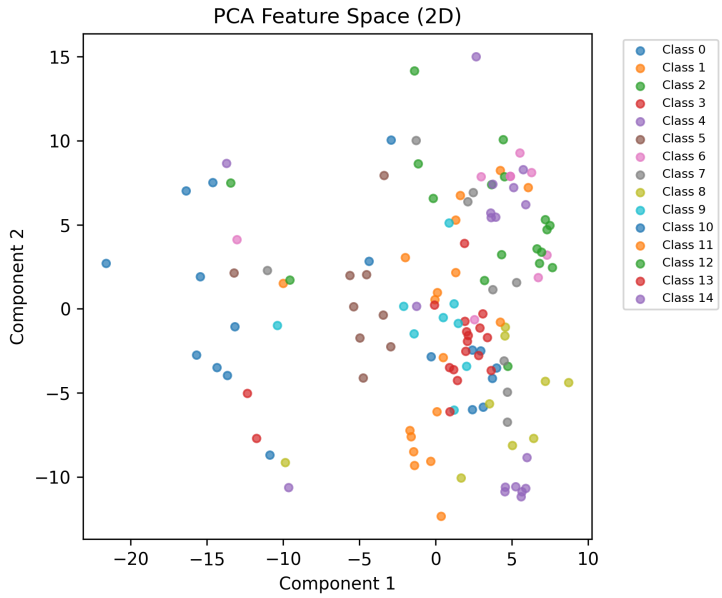

Figure 5: 2D visualization of PCA features. PCA captures maximum variance but does not explicitly separate classes, resulting in overlapping clusters.

4.5.2 LDA Feature Distribution

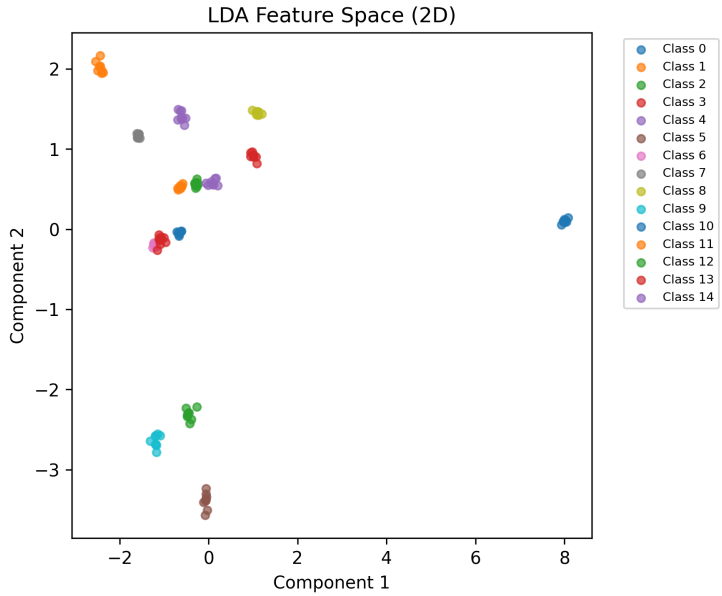

Figure 6: 2D visualization of LDA features. Compared to PCA, LDA produces better class separation by maximizing between-class variance.

4.5.3 Kernel LDA Feature Distribution

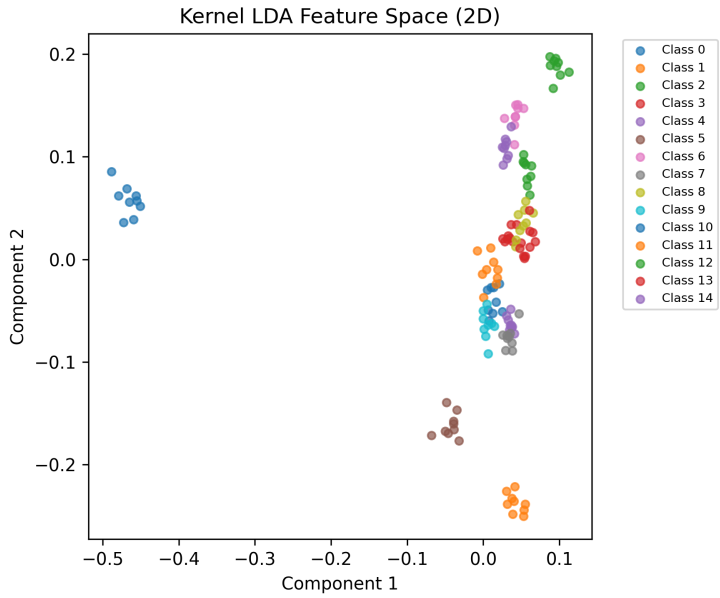

Figure 7: 2D visualization of Kernel LDA features. Kernel LDA achieves the most compact and well-separated clusters by combining nonlinear feature mapping with supervised discrimination.

Observation. PCA fails to clearly separate identities due to its unsupervised nature. LDA significantly improves class separation by using label information. Kernel LDA further enhances separability by capturing nonlinear variations in facial appearance, which explains its superior recognition accuracy.

5 Conclusion

We implemented PCA, LDA, Kernel PCA, and Kernel LDA from scratch. LDA significantly improves over PCA due to label-aware projections. Kernel PCA alone does not improve much on this dataset, but Kernel LDA (kPCA→LDA) achieves the best performance (1.000).

A Appendix: Full Code

Note: This is the complete end-to-end code used to generate all figures and accuracy results.
